To the editor,

We read with great interest the paper published by Ray Sumantra et al entitled “Malnutrition in healthcare institutions: A review of the prevalence of under-nutrition in hospitals and care homes since 1994 in England” published recently in the journal (1). This paper presents a systematic review of 16 studies about the prevalence and incidence of hospital malnutrition. Therefore, and motivated by this paper, we would like to revisit and summarize the Peruvian literature on this regard.

Hospital malnutrition, defined as the altered nutritional status, is a consequence of a deficient intake while a patient is admitted in the hospital (2). This leads to a longer hospital stay, worse treatment response, re-admissions and higher costs along with altered metabolic, biochemical and anthropometric changes. Worldwide, the prevalence is as high as 50% according to the ELAN study (2).

In Peru, four studies have been published between 2007 and 2013 and assessed the nutritional status of adult patients in several major Public Hospitals in Lima. These available studies show an overall prevalence of malnutrition in hospitals of 50% (range: 30% - 50%). This percentage is higher in populations such as the elderly admitted to hospitals, between 47.8%-68.2% (2,3). A brief summary of these selected studies sorted by chronological order of publication is shown in Table 1.

Most of the studies were focused on general medicine ward patients, one study focused on patients undergoing gastrointestinal anastomoses and one study on Cancer patients. In most of the cases the nutritional assessment was not conducted over the course of the admission so it is hard to assess the actual magnitude and evolution of the nutritional impairment. This is a very important methodological consideration since the actual way to assess the impact and magnitude of the length of stay on the anthropometric and nutritional markers of a given patient is by means of follow up. Ideally, with measurements at admission, at the moment of discharge and also in-between assessments. From the reviewed Peruvian literature, only one study, to the best of our knowledge, actually assess the key variables in a longitudinal fashion (3).

In summary, there is some Peruvian literature about this topic, mostly focused in Lima, the capital city. A comprehensive study is needed to assess the nutritional and anthropometrical status and relevant biochemical markers at both the moment of admission and over the course of the hospital stay. Even more, to spread the scope of such ideal type of studies to other settings in Peru and to a broader type of patients specially those at high risk of malnutrition given their underlying...
disease (cancer, kidney and liver diseases, inherent metabolic disorders, etc). Studies on this regard should be warranted in the Peruvian scenario.
